Evaluation of Turfgrasses and a Ground Cover Under Drought and Extreme Deficit Irrigation

Nineteen turfgrass species/cultivars and one ground cover received irrigation replacement of only 40% ETo during the summer of 2012. Which ones survived?

KURAPIA Hybrid Ground Cover

Evaluation of Turfgrasses and a Ground Cover Under Drought and Extreme Deficit Irrigation

Ryan Nichols, Alea Miehls, Jim Baird, Darrel Jenerette and Lindy Allsman
Department of Botany and Plant Sciences
University of California, Riverside

The Bottom Line: Under extreme deficit irrigation (40% ETo) and minimal natural precipitation during 2012 in Riverside, the ground cover Kurapia and warm-season turfgrass species Kikuyugrass and buffalograss performed the best in terms of color and quality. The cool-season turfgrass species were most severely impacted by water stress, resulting in significant turf loss and/or dormancy. Perennial ryegrass appeared to survive the best among the cool-season turfgrasses under the conditions of our study. Overall, these results demonstrate the benefits of using alternative species such as ground covers or warm-season turfgrasses in warm, inland climates like Riverside or when water use is severely restricted.

Introduction:

Turfgrass is a key component of urban landscapes. In Southern California, recent estimates have suggested 41% of urbanized lands are covered with turfgrass. Throughout the United States, turfgrass is the predominant irrigated crop species. Climate change resulting in increasing temperature and drought coupled with diminishing water resources offer the greatest potential for severely impacting turfgrass and landscape use. Hopefully landscape water restrictions in California will never become as severe as in this study; however, we wanted to evaluate how the major cool- and warm-season turfgrasses species are affected by drought and extreme deficit irrigation. Furthermore, we compared turfgrass performance to a low-growing ground cover 'Kurapia' (*Lippia nodiflora* L.) that was selected and developed in Japan for drought tolerance among other characteristics.

Location:	UCR Turfgrass Research Facility, Riverside, CA
Soil:	Hanford fine sandy loam
Experimental Design:	Randomized complete block with 3 replications
Plot Size:	6 ft by 10 ft
Establishment:	Turf was established by sod or plugs (buffalograss) were in July and August 2008; A-4 bentgrass, Chaparral perennial ryegrass, Tifdwarf bermudagrass, and Whittet zoysiagrass were sodded in spring of 2010; Kurapia established from plugs in spring 2011
Fertility:	2 to 4 lbs N/1000 ft^2/yr prior to June 2012; no fertilizer applied thereafter
Irrigation:	Prior to June 2012, all turfgrasses and ground cover were subjected to deficit irrigation (water stress) based on a percentage of the previous week's reference evapotranspiration (60% ET_o). Hand watering was used to maintain uniform and accurate irrigation distribution. Automatic irrigation treatment began on June 1, 2012 with 40% Eto scheduled using daily ETo estimates calculated by an on-site California Irrigation Management Information System (CIMIS) automated weather station. Rainfall of 0.1 inches or more per day was subtracted from ETo. When the accumulated ETo equaled 2.5 inches, irrigation of 1.0 inch was applied to the entire area.
Data Collected:	Monthly color and quality ratings (1 to 9, 9 = best; 6 = minimally acceptable)

Commercial Variety/Species	**Variety/Composition**	**Origin/Producer**	**Mowing Height**
Hillside Fine Fescue	'Florentine GT' Strong Creeping Red Fescue, 'Seabreeze GT' Slender Creeping Red Fescue, and 'Tiffany' Chewings Fescue.	Sod from West Coast Turf	Mow once/yr
